Computer Organization: An Overview

An Historical Interlude

Representing Numbers in Binary

Representing Text, Sound, and Pictures in Binary
Computer Organization: An Overview
The Von Neumann Architecture (1945)

Also known as the stored-program architecture
A computer is a machine that

(1) stores a very, very large number of numbers and

(2) performs very, very long specified sequences of very simple operations on these numbers

(3) very, very fast.
There are two main principles of computer organization:

1. **Levels of Abstraction**: A complex system can be described as a hierarchy of levels, where collections of interacting entities at one level are encapsulated in a single entity at a higher level.

2. **Internal vs. External Representation**: Within a complex system, the representations used internally by an entity to perform its functions need not be those with which it interacts externally with other entities.
A Historical Interlude: 
The Glory of Decimal Numbers

- Decimal numbers (base-10 positional notation) were developed around 1200 years ago in the Middle East,
- Rapidly replaced older non-positional systems, e.g.,

\[ \text{MCMXXXVII} \]
\[(1000 + (1000 - 100) + 10 + 10 + 10 + + 5 + 1 + 1)\]

vs.

\[ 1937_{10} \]
\[((1 \times 10^3) + (9 \times 10^2) + (3 \times 10^1) + (7 \times 10^0))\]
<table>

A Historical Interlude: (Cont’d)
The Tyranny of Decimal Numbers

Centrality of decimal numbers in mathematics led to their being both the internal and external representations of numbers in the earliest computing machines, e.g., the 1642 addition machine of Blaise Pascal (1623–1662).
A Historical Interlude: (Cont’d)

The Tyranny of Decimal Numbers (Cont’d)

This reliance on decimal internal representations continued into the early days of electromechanical computing.

Harvard Mark I (1944)
Zuse Z3 (1941)
Colossus (1944)
A Historical Interlude: (Cont’d)
The Glory of Binary Numbers

The emergence of fully electronic computing in the late 1940s led to binary (base-2 positional notation) internal representations of numbers.

\[ 167_{10} \]
\[ = ((1 \times 10^2) + (6 \times 10^1) + (7 \times 10^0)) \]

vs.

\[ 10100111_2 \]
\[ = ((1 \times 2^7) + (0 \times 2^6) + (1 \times 2^5) + (0 \times 2^4) + (0 \times 2^3) + (1 \times 2^2) + (1 \times 2^1) + (1 \times 2^0)) \]
A Historical Interlude: (Cont’d)
The Glory of Binary Numbers (Cont’d)

<td>$10^9 \rightarrow 1,000,000,000$</td>
<td>$2^9 \rightarrow 512$</td>
</tr>
</tbody>
</table>

In binary, need 10 digits to represent a factor of $\approx 1000$. 
Done for reliability, e.g., distinguishing between and maintaining two voltage levels is **much** easier to do than distinguishing between and maintaining ten voltage levels.

Representing Numbers in Binary

Basic base-2 positional notation (unsigned binary) can handle the representation and addition of positive integers, e.g.,

\[
\begin{align*}
1 & \ 1 \ 1 \ 1 \ 1 \\
\hline
1 & \ 1 \ 0 \ 1 \ 1 \\
+ & \ 1 \ 1 \ 0 \ 1 \\
\hline
1 & \ 0 \ 1 \ 0 \ 0 \ 0
\end{align*}
\]

\[
\begin{align*}
1 \ 1 \ 1 \ 1 & \ 1 \ 1 \ 0 \ 1 \ 1_2 \\
\hline
2 & \ 7_{10}
\end{align*}
\]

\[
\begin{align*}
+ & \ 1 \ 1 \ 0 \ 1 \ 1_2 \\
+ & \ 1 \ 3_{10}
\hline
4 & \ 0_{10}
\end{align*}
\]

\[1 \leftarrow \text{carry}\]

... But what about negative integers? ...
Representing Numbers in Binary: (Cont’d)
Sign/Magnitude Representation

- Use leftmost bit to encode sign (+ve as 0, -ve as 1), e.g.,

<table>
<thead>
<tr>
<th>Negative</th>
<th>Positive</th>
</tr>
</thead>
<tbody>
<tr>
<td>$-0_{10}$ 100$_2$</td>
<td>000$<em>2$ $+0</em>{10}$</td>
</tr>
<tr>
<td>$-1_{10}$ 101$_2$</td>
<td>001$<em>2$ $+1</em>{10}$</td>
</tr>
<tr>
<td>$-2_{10}$ 110$_2$</td>
<td>010$<em>2$ $+2</em>{10}$</td>
</tr>
<tr>
<td>$-3_{10}$ 111$_2$</td>
<td>011$<em>2$ $+3</em>{10}$</td>
</tr>
</tbody>
</table>

- Has two representations of zero, and both can arise during arithmetic; this causes problems for computer designers.
Representing Numbers in Binary: (Cont’d)
Two’s Complement Representation

- Represent negative number by taking unsigned binary positive version and starting after rightmost 1, complement every bit to the left (see also Textbook, p. 160), e.g.,

<table>
<thead>
<tr>
<th>Negative</th>
<th>Positive</th>
</tr>
</thead>
<tbody>
<tr>
<td>—</td>
<td>000₂  +0₁₀</td>
</tr>
<tr>
<td>-1₁₀</td>
<td>001₂  +1₁₀</td>
</tr>
<tr>
<td>-2₁₀</td>
<td>010₂  +2₁₀</td>
</tr>
<tr>
<td>-3₁₀</td>
<td>011₂  +3₁₀</td>
</tr>
<tr>
<td>-4₁₀</td>
<td>—</td>
</tr>
</tbody>
</table>

- Has one zero but more negative than positive numbers.
Representing Numbers in Binary: (Cont’d)
Fractional Numbers

• Store in scientific notation \((M \times B^E)\) where base \(B = 2\), mantissas \((M)\) and exponents \((E)\) are stored in signed binary notation, and mantissas are normalized, e.g.,
Example: Representing $5.75_{10}$ as a fractional number

- $5_{10} = 4 + 1 = 2^2 + 2^0 = 101_2$ and
  
  $.75_{10} = \frac{1}{2} + \frac{1}{4} = \frac{1}{2^1} + \frac{1}{2^2} = .11_2$;

  Therefore, $5.75_{10} = 101.11_2$

- Normalize $101.11_2$, e.g.,

  \[
  \begin{align*}
  101.11_2 &= 101.11_2 \times 2^0 \\
  &= 10.111_2 \times 2^1 \\
  &= 1.0111_2 \times 2^2 \\
  &= .10111_2 \times 2^3
  \end{align*}
  \]

- Encode $M = +.10111_2$ and $E = +3_{10} = +11_2$, i.e.,

  \[0 + 00010111 + 0 + 000011\]
Representing Numbers in Binary: (Cont’d)
More Compact Representations

Long binary numbers represented more compactly in octal (8 digit; 0, 1, ..., 7) or hexadecimal (16 digit; 0, 1, ..., 9, A, B, C, D, E, F), e.g.,

\[
\begin{array}{c|c|c|c|c|c}
7 & 7 & 1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 & 0 & 0 \\
\end{array} \quad \Rightarrow \quad 7711_8
\]

\[
\begin{array}{c|c|c|c|c|c}
F & C & 9 & & & \\
1 & 1 & 1 & 1 & 1 & 1 \\
\end{array} \quad \Rightarrow \quad FC9_{16}
\]
Binary Computer Memory

What does

0100000101011000110001111

mean?
Binary Computer Memory (Cont’d)

Things that binary computer memory does well:

- Numbers
- Text
- “HELLO” 8, 5, 12, 12, 15
- Sounds
- Pictures

01000#00101#01100#01100#01111

Text
"HELLO"

Numbers
8, 5, 12, 12, 15

Sounds

Pictures
Representing Text in Binary

- Associate individual symbols with unsigned binary numbers; these symbols may not be printable but rather instructions to I/O interface devices, e.g., control characters.

- Original ASCII and EBCDIC standard used 7 and 8 bits to represent 128 and 256 symbols (see Table 4.3 in textbook for part of ASCII standard).

- Original UNICODE standard used 16 bits to represent \( \approx 65,000 \) symbols; embedded original ASCII standard in lowest 128 codes.

- UNICODE subsequently extended to 32 bits; can accommodate \( \approx \) two billion symbols.
Representing Sound in Binary

- Encode periodic audio signal samples as integers.
- 40,000 samples/sec suffices for human hearing.
Representing Pictures in Binary

- Reduce picture to grid of picture elements (pixels).
- Encode pixel values as one or more integers, e.g., single bits (B/W (see below)), 8-value gray scale (B/W), triplets of 256-value red / green / blue intensities (color).
Binary Computer Memory Redux

Things that binary computer memory doesn’t do so well:

**Arbitrary Fractional Numbers**

1/3 → 0.33

1/3 → 0.33

1/3 → 0.33

**Detailed Pictures**

Earth
