COMP1002 Winter 2017 midterm exam study sheet

- *Propositional statement*: expression that has a truth value (true/false). It is a *tautology* if it is always true, *contradiction* if always false.
- Logic connectives: negation ("not") $\neg p$, conjunction ("and") $p \land q$, disjunction ("or") $p \lor q$, implication $p \rightarrow q$ (equivalent to $\neg p \lor q$), biconditional $p \leftrightarrow q$ (equivalent to $(p \rightarrow q) \land (q \rightarrow p)$). The order of precedence: \neg strongest, \land next, \lor next, \rightarrow and \leftrightarrow the same, weakest.
- If $p \to q$ is an implication, then $\neg q \to \neg p$ is its *contrapositive*, $q \to p$ a *converse* and $\neg p \to \neg q$ an *inverse*. An implication is equivalent to its contrapositive, but not to converse/inverse or their negations. A negation of an implication $p \to q$ is $p \land \neg q$ (it is not an implication itself!)
- A *truth table* has a line for each possible values of propositional variables $(2^k \text{ lines if there are } k \text{ variables})$, and a column for each variable and subformula, up to the whole statement. The cells of the table contain T and F depending whether the (sub)formula is true for the corresponding values of variables.
- A truth assignment is a string of values of variables to the formula, usually a row with values of first several columns in the truth table (number of columns = number of variables). A truth assignment is satisfying the formula if the value of the formula on these variables is T, otherwise the truth assignment is falsifying. A truth assignment can be encoded by a formula that is a \wedge of variables and their negations, with negated variables in places that have F (false) in the assignment, and non-negated that have T (true). For example, x = T, y = F, z = F is encoded as $(x \wedge \neg y \wedge \neg z)$. It is an encoding in a sense that this formula is true only on this truth assignment and nowhere else.
- Finding a method for checking if a formula has a satisfying assignment that is always significantly faster than using truth tables (that is, better than brute-force search) is a million dollar problem, known as "P vs. NP".
- Two formulas are *logically equivalent* if they have the same truth table. The most famous example of logically equivalent formulas is $\neg(p \lor q) \equiv (\neg p \land \neg q)$ (with a dual version $\neg(p \land q) \equiv (\neg p \lor \neg q)$) where p and q can be arbitrary (propositional, here) formulas. These pairs of logically equivalent formulas are called *DeMorgan's law*.
- There are several other important pairs of logically equivalent formulas, called *logical identities* or *logic laws*. We will talk more about them when we talk about Boolean algebras. Here, just remember that $FALSE \land p \equiv p \land \neg p \equiv FALSE$, $FALSE \lor p \equiv TRUE \land p \equiv p$ and $TRUE \lor p \equiv p \lor \neg p \equiv TRUE$.
- A set of logic connectives is called *complete* if it is possible to make a formula with any truth table out of these connectives. For example, \neg , \wedge is a complete set of connectives, and so is the Sheffer's stroke | (where $p|q \equiv \neg(p \land q)$), also called NAND for "not-and". But \lor , \wedge is not a complete set of connectives since then it is impossible to express a truth table with 0 when all variables are 1.
- An argument consists of several formulas called *premises* and a final formula called a *conclusion*. If we call premises $A_1 \ldots A_n$ and conclusion B, then an argument is *valid* iff premises imply the conclusion, that is, $A_1 \land \cdots \land A_n \to B$. We usually write them in the following format:

Today is either Thursday or Friday On Thursdays I have to go to a lecture Today is not Friday (alternatively, On Friday I have to go to the lecture)

 \therefore I have to go to a lecture today

- A valid form of argument is called *rule of inference*. The most prominent such rule is called *modus ponens*.
 - $\begin{array}{c} p \to q \\ p & ---- \\ \therefore q \end{array}$
- There are several main types of proofs depending on the types of rules of inference used in the proof. The main ones are *direct proof, by contraposition, by contradiction* and *by cases*.
- There are two main normal forms for the propositional formulas. One is called *Conjunctive normal* form (CNF) and is an ∧ of ∨ of either variables or their negations (here, by ∧ and ∨ we mean several formulas with ∧ between each pair, as in (¬x ∨ y ∨ z) ∧ (¬u ∨ y) ∧ x. A *literal* is a variable or its negation (x or ¬x, for example). A ∨ of (possibly more than 2) literals is called a *clause*, for example (¬u ∨ z ∨ x), so a CNF is true for some truth assignment whenever this assignment makes each of the clauses is true, that is, each clause has a literal that evaluates to true under this assignment. A *Disjunctive normal form* (DNF) is like CNF except the roles of ∧ and ∨ are reversed. A ∧ of literals in a DNF is called a *term*. To construct canonical DNF and a CNF, start from a truth table and then for every satisfying truth assignment ∨ its encoding to a DNF, and for every falsifying truth assignment ∧ the negation of its encoding to the CNF, and apply DeMorgan's law. This may result in a very large CNFs and DNFs, comparable to the size of the truth table itself (2^{number of variables}).
- A resolution proof system is used to find a contradiction in a formula (and, similarly, to prove that a formula is a tautology by finding a contradiction in its negation). Resolution starts with a formula in a CNF form, and applies the rule "from clause $(C \lor x)$ and clause $(D \lor \neg x)$ derive clause $(C \lor D)$ until a falsity F (equivalently, empty clause ()) is reached (so in the last step one of the clauses being resolved contains just one variable and another clause being resolved contains just that variable's negation. Resolution can be used to check the validity of an argument by running it on the \land of all premises (converted, each, to a CNF) \land together with the negation of the conclusion.
- Pigeonhole principle If n pigeons sit in n-1 holes, so that each pigeon sits in some hole, then some hole has at least two pigeons. Can be used to show, for example, that there are two people in our class who carry the same number of pens. There is no small resolution proof of the pigeonhole principle.
- Boolean functions are functions which take as argument boolean (ie, propositional) variables and return 1 or 0 (or, the convention here is 1 instead of T, and 0 instead of F). Each Boolean function on n variables can be fully described by its truth table. A size of a truth table of a function on n variables is 2^n . Even though we often can have a smaller description of a function, vast majority of Boolean functions cannot be described by anything much smaller. Every Boolean function can be described by a CNF or DNF, using the above construction.

Predicate logic:

- A *predicate* is like a propositional variable, but with *free variables*, and can be true or false depending on the values of these free variables. A *domain* of a predicate is a set from which the free variables can take their values (e.g., the domain of Even(n) can be integers).
- Quantifiers For a predicate P(x), a quantified statement "for all" ("every", "all") $\forall x P(x)$ is true iff P(x) is true for every value of x from the domain (also called universe); here, \forall is called a *universal quantifier*. A statement "exists" ("some", "a") $\exists x P(x)$ is true whenever P(x) is true for at least one element x in the universe; \exists is an existential quantifier. The word "any" means sometimes \exists and sometimes \forall . A domain (universe) of a quantifier, sometimes written as $\exists x \in D$ and $\forall x \in D$ is the set of values from which the possible choices for x are made. If the domain of a quantifier is empty, then if the quantifier is a part of the formula (akin to a piece of code) on which the variable under that quantifier can be used (after the quantifier symbol/inside the parentheses/until there is another quantifier over a variable with the same name). A variable is *bound* if it is under a some quantifier symbol, otherwise it is free.
- First-order formula A predicate is a first-order formula (possibly with free variables). A \land, \lor, \neg of first-order formulas is a first-order formula. If a formula A(x) has a free variable (that is, a variable x that occurs in some predicates but does not occur under quantifiers such as $\forall x$ or $\exists x$), then $\forall x A(x)$ and $\exists x A(x)$ are also first-order formulas.
- Negating quantifiers. Remember that $\neg \forall x P(x) \equiv \exists x \neg P(x)$ and $\neg \exists x P(x) \equiv \forall x \neg P(x)$.
- Reasoning in predicate logic The rule of universal instantiation says that if some property is true of everything in the domain, then it is true for any particular object in the domain. A combination of this rule with modus ponens such as what is used in the "all men are mortal, Socrates is a man : Socrates is mortal" is called universal modus ponens.
- Normal forms In a first-order formula, it is possible to rename variables under quantifiers so that they all have different names. Then, after pushing negations into the formulas under the quantifiers, the quantifier symbols can be moved to the front of a formula (making their scope the whole formula).
- Formulas with finite domains If the domain of a formula is finite, a formula can be converted into a propositional formula by changing each $\forall x$ quantifier with a \land of the formula on all possible values of x; an \exists quantifier becomes a \lor . Then terms of the form P(value) (e.g., Even(5)) are treated as propositional variables.
- *Limitations of first-order logic* There are concepts that are not expressible by first-order formulas, for example, transitivity ("is there a flight from A to B with arbitrary many legs?" cannot be a database query described by a first-order formula).

Proof strategies

• Existential statement: $\forall x F(x)$. Constructive proof: give an example satisfying the formula under the quantifier (e.g, exists x which is both even and prime: take n = 2), then conclude by the *existential generalization rule* that $\exists x F(x)$ is true. Non-constructive proof: If the proof says $\exists n P(n)$, show that assuming $\forall n \neg P(n)$ leads to contradiction.

- Universal statement: $\forall x F(x)$. To prove that it is false, give a counterexample. To prove that it is true, start with the *universal instantiation*: take an arbitrary element, give it a name (say n), and prove that F(n) holds without any additional assumptions. By *universal generalization*, conclude that $\forall x F(x)$ holds.
- To prove F(n)
 - Direct proof: show that F(n) holds directly, using definition, algebra, etc. If F(n) is of the form $G(n) \to H(n)$, then assume G(n) and derive H(n) from this assumption. Examples: sum of even integers is even, if $n \equiv m \pmod{d}$ then there is $k \in \mathbb{Z}$ such that n = m + kd, if n is odd then $n^2 \equiv 1 \pmod{8}$, Pythagores theorem.
 - Proof by cases If F(x) is of the form $(G_1(x) \lor G_2(x) \lor \cdots \lor G_k(x)) \to H(x)$, then prove $G_1(x) \to H(x)$, $G_2(x) \to H(x) \ldots G_k(x) \to H(x)$. Examples: sum of two consecutive integers is odd, $\forall x, y \in \mathbb{R} | x + y | \le |x| + |y|$, $\min(x, y) = (x + y |x y|)/2$, $k^2 + k$ is even.
 - Proof by contraposition If F(n) is of the form $G(n) \to H(n)$, can prove $\neg H(n) \to \neg G(n)$ (that is, assume that H(n) is false, and derive that G(n) is false). Examples: pigeonhole principle, if a square of an integer is even, then integer itself is even.
 - Proof by contradiction To prove F(n), show that $\neg F(n) \rightarrow FALSE$. Examples: $\sqrt{2}$ is irrational, there are infinitely many primes.
- Some definitions:
 - An $n \in \mathbb{Z}$ is even if $\exists k \in \mathbb{Z}$ such that n = 2k. An $n \in \mathbb{Z}$ is odd if $\exists k \in \mathbb{Z}$ such that n = 2k + 1. An $n \in \mathbb{Z}$ is divisible by $m \in \mathbb{Z}$ if $\exists k \in \mathbb{Z}$ such that n = km.
 - Modular arithmetic: for any $n, d \neq 0 \in \mathbb{Z} \exists q, r \in \mathbb{Z}$ such that n = qd + r and $0 \leq r < d$. Here, q is a quotient and r is a remainder. Congruence: for $n, m, d \neq 0 \in \mathbb{Z}$, $n \equiv m \pmod{d}$ ("n is congruent to m mod d") iff $\exists q_1, q_2, r \in \mathbb{Z}$ such that $0 \leq r \leq d$, $n = q_1d + r$ and $m = q_2d + r$. That is, n and m have the same remainder modulo d.
 - Absolute value of $x \in \mathbb{R}$, denoted |x|, is x if $x \ge 0$ and -x if x < 0.

Set Theory

- A set is a well-defined collection of objects, called elements of a set. An object x belongs to set A is denoted $x \in A$ (said "x in A" or "x is a member of A"). Usually for every set we consider a bigger "universe" from which its elements come (for example, for a set of even numbers, the universe can be all natural numbers). A set is often constructed using set-builder notation: $A = \{x \in U | P(x)\}$ where U is a universe , and P(x) is a predicate statement; this is read as "x in U such that P(x)" and denotes all elements in the universe for which P(x) holds. Alternatively, for a small set, one can list its elements in curly brackets (e.g., $A = \{1, 2, 3, 4\}$.)
- A set A is a subset of set B, denoted $A \subseteq B$, if $\forall x (x \in A \to x \in B)$. It is a proper subset if $\exists x \in B$ such that $x \notin A$. Otherwise, if $\forall x (x \in A \leftrightarrow x \in B)$ two sets are equal.
- Special sets are: *empty set* \emptyset , defined as $\forall x (x \notin \emptyset)$. Universal set U: all potential elements under consideration at given moment. Natural numbers \mathbb{N} (here, $0 \in \mathbb{N}$), integers \mathbb{Z} , rationals \mathbb{Q} , reals \mathbb{R} .

Name	Logic law	Set theory law	Boolean algebra law
Double Negation	$\neg \neg p \equiv p$	$\overline{\overline{A}} = A$	$\overline{\overline{x}} = x$
DeMorgan's laws	$\neg (p \lor q) \equiv (\neg p \land \neg q)$	$\overline{A \cup B} = \overline{A} \cap \overline{B}$	$\overline{x+y} = \overline{x} \cdot \overline{y}$
	$\neg (p \land q) \equiv (\neg p \lor \neg q)$	$\overline{A \cap B} = \overline{A} \cup \overline{B}$	$\overline{x \cdot y} = \overline{x} + \overline{y}$
Associativity	$(p \lor q) \lor r \equiv p \lor (q \lor r)$	$(A \cup B) \cup C = A \cup (B \cup C)$	(x+y) + z = x + (y+z)
	$(p \wedge q) \wedge r \equiv p \wedge (q \wedge r)$	$(A \cap B) \cap C = A \cap (B \cap C)$	$(x \cdot y) \cdot z = x \cdot (y \cdot z)$
Commutativity	$p \lor q \equiv q \lor p$	$A \cup B = B \cup A$	x + y = y + x
	$p \wedge q \equiv q \wedge p$	$A \cap B = B \cap A$	$x \cdot y = y \cdot x$
Distributivity	$p \land (q \lor r) \equiv (p \land q) \lor (p \land r)$	$A \cap (B \cup C) = (A \cap B) \cup (A \cap C)$	$x \cdot (y+z) = (x \cdot y) + (x \cdot z)$
	$p \lor (q \land r) \equiv (p \lor q) \land (p \lor r)$	$A \cup (B \cap C) = (A \cup B) \cap (A \cup C)$	$x + (y \cdot z) = (x + y) \cdot (x + z)$
Idempotence	$(p \lor p) \equiv p \equiv (p \land p)$	$A\cup A=A=A\cap A$	$x + x = x = x \cdot x$
Identity	$p \lor F \equiv p \equiv p \land T$	$A\cup \emptyset = A = A\cap U$	$x + 0 = x = x \cdot 1$
Inverse	$p \lor \neg p \equiv T$	$A \cup \bar{A} = U$	$x + \bar{x} = 1$
	$p \land \neg p \equiv F$	$A \cap \bar{A} = \emptyset$	$x \cdot \bar{x} = 0$
Domination	$p \lor T \equiv T$	$A \cup U = U$	x + 1 = 1
	$p \wedge F \equiv F$	$A \cap \emptyset = \emptyset$	$x \cdot 0 = 0$

Table 1: Laws of boolean algebras, logic and sets

- A power set for a given set A, denoted 2^A or $\mathcal{P}(A)$, is the set of all subsets of A. If A has n elements, then 2^A has 2^n elements (since for every element there are two choices, either it is in, or not).
- Basic set operations are a complement \overline{A} , denoting all elements in the universe that are not in A, then union $A \cup B = \{x | x \in A \text{ or } x \in B\}$, and intersection $A \cap B = \{x | x \in A \text{ and } x \in B\}$ and set difference $A B = \{x | x \in A \text{ and } x \notin B\}$. Lastly, the Cartesian product of two sets $A \times B = \{(a, b) | a \in A \text{ and } b \in B\}$.
- To prove that $A \subseteq B$, show that if you take an arbitrary element of A then it is always an element of B. To prove that two sets are equal, show both $A \subseteq B$ and $B \subseteq A$. You can also use set-theoretic identities.
- A cardinality of a set is the number of elements in it. Two sets have the same cardinality if there is a bijection between them. If the cardinality of a set is the same as the cardinality of \mathbb{N} , the set is called *countable*. If it is greater, then *uncountable*.
- Principle of inclusion-exclusion: The number of elements in $A \cup B$, $|A \cup B| = |A| + |B| |A \cap B|$. In general, add all odd-sized intersections and subtract all even-sized intersections.
- Boolean algebra: A set B with three operations +, · and ⁻, and special elements 0 and 1 such that 0 ≠ 1, and axioms of identity, complement, associativity and distributivity. Logic is a boolean algebra with F being 0, T being 1, and ⁻, +, · being ¬, ∨, ∧, respectively. Set theory is a boolean algebra with Ø for 0, U for 1, and ⁻, ∪, ∩ for ⁻, +, ·. Boolean algebra is sound and complete: anything true is provable (completeness) and anything provable is true (soundness).
